

The chromosome IV locus, and the genes under it

JU1793 × JU2466 F2 pools. The trace is the JU1793 allele frequency with a 95% band, so a rise means selection for the JU1793 allele. Shaded bands are the two contrasts' support intervals, triangles their chrIV peaks. The JU1793 allele sits near 0.25 in the untreated control across this whole window, rises to about 0.78 under *mig-6* RNAi and about 0.61 under *pos-1* — enriched under **both** knockdowns. That is the general-RNAi-response signature, and unlike the chrX locus. Below the line, all 222 protein-coding gene models in the window. Every gene carrying loss-of-function variation between the parents is marked: **drh-1** in red (the red stripe is *niDf250*), the others in **blue**. Truncating SNVs and indels plus PASS structural variants overlapping a CDS; missense is not counted. The traces are flat across megabases, so position alone singles out none of them.
