

A T96 is extracellular, in a β -strand

Topology from DeepTMHMM; secondary structure from the Kabsch & Sander hydrogen-bond criterion. The extracellular domain is β -rich and T96 lies in a strand. V5L, the only other protein-altering difference between the cross parents in this interval, falls in the signal peptide.

B AlphaFold3 model, extracellular domain

Residues 21–193 of chain A. T96 and the preceding loop residue N94 are marked; both sit at the surface of the β -sandwich. The extracellular domain is the only part of the model in the confident pLDDT band (mean 72.3; T96 79.3), and the predicted dimer interface is not credible (ipTM 0.46), so neither the membrane-proximal region nor the dimer is shown.

C Residue 96 contributes in both directions

Embryos hatched on *pos-1* RNAi. Editing 96T→K in JU1793 removes most of its resistance and 96K→T in JU2466 recovers part of it, so residue 96 contributes in both directions but does not account for the whole difference between the parents. One plate per strain; bars are Wilson 95% intervals on that plate's embryo count. HT115 controls, 97.7–100% throughout, are in the supplement.
