

A The allele does not split the panel

Every phenotyped strain in the 2023 panel (230 of 231 genotyped), split by residue 96. 96K is at 36% frequency. The distributions are not distinguishable: Wilcoxon $p = 0.99$. The means differ in the direction the crosses predict (96K more sensitive) but only because the 96T group holds the resistant tail — Welch $p = 0.15$, $r^2 = 0.007$. Open circles are the four strains whose allele is known independently.

B Nor is it a signal in the scan

GEMMA LOCO on the same trait, 300 kb either side of the variant. The T96K marker itself reaches $-\log_{10}p = 0.62$ ($p = 0.24$), ranking 18,662 of

64,423 markers on chromosome III; nothing within 300 kb clears either threshold. The chromosome III peak for this trait is at 5.97 Mb, 7.7 Mb away. *sid-2* was found by the cross and the NILs, not here.
