

A

The same experiment, scored six ways

Red is the 81 strains absent from every pos-1 pool. On the absolute scales they sit inside the distribution; log2fc as shipped throws them to $-58..-69$, far outside the observed range of $-9.9..6.8$; the censored codings put them at the responsive end without inventing an order among them.

B

On the absolute scale, response magnitude is mostly starting abundance

$\text{Spearman}(|\text{delta}|, \text{control frequency}) = +0.856$. The dashed line is $|\text{delta}| = \text{control frequency}$, which is exactly where the 81 absent strains must fall: their pos-1 frequency is 0, so their delta IS minus their starting abundance. They are not censored on this scale -- they are exactly observed -- but what is observed about them is largely how abundant they were.
