

Sample-level frequencies behind the Figure 1 slopes

One facet per sample, one point per wild isolate, for the 15 samples the slope fits use (non-baseline, day 17 excluded). Vertical bars are 95% percentile intervals over 100 bootstrap replicates of the deconvolution, taken at the sample level; the MIP-seq frequencies are published point values and carry no interval. Dashed line is $y = x$, not a fit. N2 excluded. 221 of 1,470 points (15%) are exact NNLS zeros, where the non-negativity constraint drops a strain from the pool; the MIP-seq table reports no zeros. Rows are one replicate arm's time course.
